

A synopsis of *Galianthe* (Rubiaceae) in Rio Grande do Sul, Southern Brazil, and a new endemic species from Serra Geral

Javier Elías Florentín¹, Mariela Nuñez Florentín¹ and Elsa Leonor Cabral¹

Received: April 12, 2017

Accepted: June 19, 2017

ABSTRACT

Thirteen species of the genus *Galianthe* have been recorded for state of Rio Grande do Sul, Brazil. The species are distributed among seven biomes, one of which contains all thirteen taxa—Subtropical Seasonal Forest. Herein a new endemic species, *G. riograndensis* J. Florentín & E.L. Cabral, is described, illustrated and differentiated from all other species of the genus by having 3-4 verticillate leaves and a long bifid style. In addition, the pollen grain morphology and the seed micromorphology of the new species are described and illustrated, and the conservation status assessed according to IUCN criteria. Moreover, *G. chodatiana* is recorded for the first time from the state, and a lectotype for *G. equisetoides* is designated. Most of the species of *Galianthe* are described and illustrated with detailed photos of living specimens. A taxonomic key for species identification, as well as comments on distribution, overall phenology and habitat, are also presented. The distribution of the new species is discussed in the context of the biogeographic region of the state, and maps and a table of species by biome are also provided.

Keywords: *Galianthe*, Rubioideae, Southern Brazil, Spermacoeeae, taxonomy.

Introduction

Recent molecular phylogenetic studies have demonstrated that *Galianthe* (Rubiaceae) belongs to the *Spermacoce* clade (Kårehed *et al.* 2008; Salas *et al.* 2015), is monophyletic and is most closely related to *Carajasia* and *Schwendenera*, with both sharing the presence of pollen grains with a double reticulum (Salas *et al.* 2015). The genus is Neotropical, with the exception of a single taxon living in Mesoamerica (*G. brasiliensis* subsp. *angulata*), is widespread in South America (Cabral & Bacigalupo 1997; Cabral 2009), with the majority of species occurring in Brazil (37 species). The species occur in *campos rupestres* (quartzitic rock outcrops), *cerrado* (savanna), low land grasslands, *campos de altitude* (highland grasslands), *caatinga* vegetation (seasonally dry

tropical forests) and savanna hillsides; in lateritic, sandy soils or with rock outcrops. Exceptionally, there are some shade-loving species, which occur in the understory of forests and woodlands, such as *G. hispidula*, *G. brasiliensis*, and *G. laxa* (Cabral & Bacigalupo 1997; Cabral 2009; Cabral & Salas 2015; Carmo *et al.* 2016). *Galianthe* comprises 50 species grouped in two subgenera: *Galianthe* subg. *Galianthe*, with 40 species, and *Galianthe* subg. *Ebelia*, with 10 species (Cabral & Bacigalupo 1997; Cabral 2009). In floristic surveys of Rio Grande do Sul, Rambo (1962) and Porto *et al.* (1977) recorded 10 and 7 species of *Galianthe*, respectively, for the state, under *Borreria* and *Diodia*, generic names linked to *Galianthe* based principally on fruit dehiscence. *Galianthe* differs from the remaining genera of the *Spermacoce* clade by having an erect habit generally with xylopodium, distylous flowers arranged in lax thyrsoid inflorescences, plump or

* Corresponding author: florentinjaviere@gmail.com

complanate seeds with wing-like margins, pollen with a double reticulum, and a basic chromosome number of $x=8$ (Cabral 2009).

Since new data regarding this genus has become available for Rio Grande do Sul, and because previous taxonomic revisions and regional checklists have become outdated (Rambo 1962; Porto *et al.* 1977; Cabral 2002), an updated taxonomy of *Galianthe* is needed.

As a result of taxonomic studies of the tribe Spermacoeeae for the Flora do Brasil 2020, a new species, *Galianthe riograndensis*, was recognized. Therefore, the aims of the present study are to: present an illustrated morphological description and a conservation assessment for the new taxa. The new species is also included in an identification key for all species of *Galianthe* recorded in the state of Rio Grande do Sul, along with maps, tables, and comments about the geographic distribution and habitats of the species.

Materials and methods

Descriptions were made by analyzing live specimens and herbarium material from the collections deposited at the herbaria B, BR, CRI, CTBS, CTES, EAC, FLOR, FUEFS, FUEL, FURB, HAS, HBR, HDCE, HPL, HUCS, HVAT, IAC, IBGE, ICN, INPA, JOI, K, LIL, MBM, MO, MPUC, MVFA, NY, P, PACA, R, RB, SI, SP, UB, UEC [acronyms according to Thiers (2017)]. Additionally, databases of Lista de Espécies da Flora do Brasil and Missouri Botanical Garden were consulted. Distribution, habitat, details of flower or fruits, and phenological data were recorded from specimen labels and field observations. In order to illustrate features or structures not or poorly shown in previous literature, a detailed photographic record of diagnostic vegetative and floral features was made (except for *Galianthe riograndensis* J. Florentín & E.L. Cabral and *G. verbenoides* (Cham. & Schltdl.) Griseb.). Vegetative and reproductive characters were measured on living and pressed specimens using a digital caliper. To analyze the distribution of species by biome, specimens were georeferenced using Google Earth (2015) and plotted in DIVA-GIS (Hijmans 2013). We followed the classification of the vegetation of Southern Brazil proposed by Iganci *et al.* (2011), who modified the classification of Leite (2002).

Pollen grains of *Galianthe riograndensis* were acetolyzed according to Erdtman (1966) and mounted in glycerine jelly for analysis by light microscopy (LM). Conventional parameters (P = polar axis, E = equatorial axis) of at least 20 grains were measured under LM, and the exine was analyzed using scanning electron microscopy (SEM). Seeds were also analyzed using SEM. For SEM analyses, seeds and acetolyzed pollen grains were sputter-coated with gold, and then photographed with a Jeol 5800 LV SEM (scanning electron microscopy service of the SGCT-UNNE, Corrientes, Argentina). Pollen terminology follows Punt *et al.* (2007) and seed terminology follows Stearn (1986).

Conservation status was assessed according to IUCN criteria (2001). The extent of occurrence (EOO) and the area of occupancy (AOO) were estimated using GeoCAT (Bachman *et al.* 2011).

Results and discussion

Taxonomic treatment

Galianthe Griseb., Symb. Fl. Argent. 24: 156. 1879.
Type: *Galianthe fastigiata* Griseb. (For synonymy and commentaries about the types see Cabral & Bacigalupo 1997).

Subshrubs, erect or decumbent, exceptionally scandent, with or without xylopodium; stems winged or not, glabrous or pubescent. Stipular sheath with 1-multifimbriate margin, covering part of the internode above the corresponding leaf pair or at the same level of the leaf pair. Leaves opposite, frequently pseudo-vorticillate, sessile; leaf blades entire, chartaceous or coriaceous. Inflorescences thyrsoid, cymose or partial inflorescences in dichasium more or less condensed, fascicles or heads; in the main and/or secondary branches. Flowers 4-merous, actinomorphic, distylous, the short-styled flowers (SS flowers) slightly larger than the long-styled flowers (LS flowers); calyx 4-lobated, rarely 2, with intercalary teeth between lobes, sometimes colletertipped; corolla infundibuliform or campanulate, white, exceptionally pale pink or lilac, internally with moniliform hairs with the same or different arrangement between both floral morphs; stamens 4, filaments of variable length in SS flowers and LS flowers, anthers dorsifix; nectariferous disk entire or 2-lobed; ovary 2-locular, each locule 1-ovulate; style with bifid stigma. Capsule septicidal with dehiscent or indehiscent valves. Seeds plump or dorsoventrally flattened, winged, with strophiole on the ventral face, persistent or caducous.

Distribution of species

Regions of greatest concentration, diversification and endemism of species of *Galianthe* are in Brazil, especially in the Brazilian *cerrado*, with 37 taxa, 21 of which are endemic (Cabral 2002; Flora do Brasil 2020). In the state of Rio Grande do Sul there are 13 species of which only one is endemic. The species described herein, *G. riograndensis*, is from the Reserve "Ibicuí-Mirim" in Santa Maria. Some species occur in restricted areas of the Southern Region of the country, such as *G. latistipula* (states of Rio Grande do Sul and Santa Catarina), and *G. verbenoides* and *G. chodatiana* (states of Rio Grande do Sul, Santa Catarina and Paraná), while the remaining species have wider distributions.

According to phytoecological studies of Southern Brazil, Leite (2002) recognized ten different phytoecological units and three transitional vegetation areas based on geology, terrain, climate, and soil. Iganci *et al.* (2011) modified the

classification of Leite (2002), and recognized nine biomes, of which seven occur in the state of Rio Grande do Sul: Tropical Forest (TRF), Tropical Coastal Scrub (TCS), Subtropical Seasonal Forest (SSF), Subtropical Mixed Forest (SMF), Subtropical Highland Grasslands (SHG, synonymous with *Campos de Cima da Serra*), Temperate Shrubland (TES) and Low Altitude Temperate Grasslands (LTG). The 13 species of *Galianthe* from Rio Grande do Sul (Fig. 1A-B, Tab. 1), inhabit the Subtropical Seasonal Forest (SSF) and share other biomes, except for *Galianthe riograndensis* which has been recorded only in SSF (Fig. 1B). According to Leite (2002), these forests are characterized by possessing a climate of with two seasons, which differ markedly in temperature: one season (summer) of up to 5 months with an average temperature above 20 °C, and the other season (winter) of up to two months with an average temperature below 15 °C. The seasonal forests exhibit varying structure that can be grouped into four strata. The first stratum is composed of tall and emergent trees, while the second is composed of dense trees of uniform height. In spring and summer, these upper strata are covered by dense foliage, which is lost during the winter season, giving to the forests a deciduous appearance. The third stratum is composed of young trees and the fourth is characterized by having more or less densely distributed shrubs. Species of *Galianthe* have a greater representation in this latter stratum, and especially in more open areas and forest edges.

New species

Galianthe riograndensis J. Florentín & E.L. Cabral sp. nov. Type: Brazil. Rio Grande do Sul: Campo dos Barcelos, 8 December 1990, N. Silveira 7963 (Holotype HAS; Isotype CTES!) (Figs. 2-3).

Galianthe riograndensis is similar to *G. equisetoides* in having stems constricted at nodes, elliptic leaves, and plump seeds, but differs in having 3-4 verticillate leaves, without brachyblasts, elliptic or narrowly elliptic leaf blades with 2-3 secondary veins [vs. 2 (-3) pseudoverticillate leaves, with axillary brachyblasts, linear or filiform leaf blades with inconspicuous secondary veins]; corolla on SS flowers 8.5-10 mm long, and LS flowers 8.5-9.6 mm long, internally with a fringe of moniliform hairs distributed from the middle of the corolla tube to the lower half of the corolla lobes, and a long bifid style (vs. corolla 4.5-6 mm long, corolla only with a ring of moniliform hairs in the corolla tube, style not divided) (Tab. 2).

Subshrubs erect, 0.6–1.5 m tall, with xylopodium; 2-3 stems per plant, simple, cylindrical to subtetragonal, fistulose, glabrous, constricted at nodes, without brachyblasts, internodes 9–15 cm long. Stipular sheath 9–14 mm long, glabrous, with 3–6 fimbriae; fimbriae 5–7 mm long. Leaves (3) 4 verticillate, sessile, leaf blades

elliptic or narrowly elliptic, 30–100 × 7–13 mm, base acute, apex attenuate and margin revolute, coriaceous, glabrous, discolorous, with 2–3 pairs of secondary veins visible on the abaxial surface. Inflorescences thyrsoid, terminal. Flowers with hypanthium 1.5–2 mm long, glabrous; calyx 4-lobed, lobes 1–1.5 mm long, triangular, glabrous, intercalary colleters; corolla infundibuliform, white or pale lilac, floral bud lilac or pink, externally papillose, internally with fringe of moniliform hairs distributed from middle of corolla tube to lower half of corolla lobes; SS flower with corolla 8.5–10 mm long, corolla lobes 3–5 mm long; stamens exerted, filaments 3–3.5 mm long, anthers 1.5–2.5 mm long; style 4.5–5 mm long, deeply divided, stigma 3–4 mm long, bifid, filiform, papillate. LS flower with corolla 8.5–9.6 mm long, corolla lobes 3.4–4.8 mm long; filaments 1 mm long, anthers 1.55–2 mm long; style 8.5–9.5 mm long, deeply divided, stigma 2.8–3.5 mm long, filiform, papillate. Nectariferous disk entire. Capsule 4.5–6 mm long, subcylindrical, glabrous, with dehiscent valves. Seeds 3–3.5 mm long, subcylindrical, dark brown, dorsal surface convex, ventral surface ± flat, with a longitudinal groove partially covered by a caducous strophiole; testa reticulate-foveate, cells polygonal or nearly circular, 55–110 µm wide, anticlinal walls straight, periclinal walls concave.

Pollen morphology: Pollen grains 8–9 zonocolporate (SS flowers), 7–8 zonocolporate (LS flowers), medium-sized, pollen of SS flowers larger than that of LS flowers (SS flowers: P=44.1–48.8 µm, and E= 46.4–51.6 µm; LS flowers: P=40.1–44.4 µm and E= 43.3–46.6 µm). Oblate spheroidal (P/E= 0.91–0.96), outline circular in polar view. Ectocolpus 22.3–28.3 µm long. Endoporus 4.9–7.2 µm long. Exine 3.7–5.5 µm thick, semitectate-bireticulate. Infrareticulum complete, nanogranulate; suprareticulum complete, muri mostly psilate; muri 0.3–0.5 µm, lumina 0.8–1.8 µm.

Distribution, habitat, and phenology: *Galianthe riograndensis* is known only from “Reserva Biológica do Ibicuí Mirim”, located on the border between the municipalities of São Martinho da Serra and Itaara, in the southern region of Serra Geral, in the southern highlands of Brazil (state of Rio Grande do Sul). This species inhabits the geographic center of the state in an ecotonal region composed of hillsides with basaltic rocky fields and seasonal forest. Flowering occurs from October to February, and fruiting from March to June.

Observation: The specimen M. L. Abruzzi 1644, included as paratype of this species, was incorrectly designated by Cabral (2009) as a neotype of *Galianthe equisetoides* (Cham. & Schldl.) E.L. Cabral.

Etymology: The epithet “*riograndensis*” refers to the distribution of the species in the state of Rio Grande do Sul and to it being endemic to the state.

Conservation status: According to IUCN criteria (IUCN 2012) *Galianthe riograndensis* should be classified as endangered [EN B2ab(ii, iii)]. The extent of occurrence (EOO) is calculated to be 15237 km², and the area of

Key to species of the genus *Galianthe* native to Rio Grande do Sul, Southern Brazil

1. Habit erect or scandent; stems never winged; fruit with dehiscent valves 2
- 1'. Habit erect or decumbent; stems frequently winged; fruit with indehiscent valves 11
2. Stems with xylopodium; inflorescences only on the main stems 3
- 2'. Stems without xylopodium; inflorescences on main and secondary stems 10
3. Stipular sheath at level of the separation of the pair of leaves 4
- 3'. Stipular sheath extended over the separation of the pair of leaves 8
4. Stems constricted at nodes, glabrous. Seeds not winged 5
- 4'. Stems not constricted at nodes, pubescent or glabrous. Seeds winged 6
5. Stipular sheath 3.8-4.7 mm long; leaves 2-3 pseudoverticillate, with inconspicuous secondary veins; corolla white; LS corolla 4.5-5 mm long; SS corolla flower 5-6 mm *G. equisetoides*
- 5'. Stipular sheath 9-14 mm long; leaves (3) 4 verticillate, with 2-3 conspicuous secondary veins; corolla pale lilac or pinkish; LS corolla 8.5-9.6 mm long; SS corolla 8.5-10 mm long *G. riograndensis*
6. Stems and leaves glabrous or papillate; leafblade 0.2-4 mm wide, with secondary veins inconspicuous; nectariferous disk entire *G. thalictroides*
- 6'. Stems and leaves pubescent or pilose; leafblade 3-28 mm wide, with conspicuous secondary veins; nectariferous disk bilobate 7
7. Plants 0.8-2.5 m tall; stems angles with retrorse hairs; stems, leaves, flowers, and fruits pilose *G. valerianoides*
- 7'. Plants 0.35-1 m tall; stems angles without retrorse hairs; stems, leaves, flowers, and fruits pubescent *G. centranthoides*
8. Stem glabrous; leaves opposite, without axillary brachyblasts and basal leaves in rosette; seeds not winged *G. fastigiata*
- 8'. Stem glabrous or with scattered and retrorse hairs; leaves pseudoverticillate by the presence of axillary leafy brachyblasts; basal leaves never in rosette; winged seeds 9
9. Stem single, glabrous; leaves glabrous; stipular sheath prolonged above the separation of the pair of leaves, 5-7 mm long, glabrous, with irregular margin with a remarkable central fimbria, triangular, acuminate, and shorter lateral fimbriae *G. latistipula*

- 9'.** Stems with lateral branches with scattered hairs; leaves pubescent; stipular sheath with a brief prolongation above the separation of the pair of leaves, 3-5 mm long, pilose or pubescent, with 6-7 fimbriae of equal length *G. chodatiana*
- 10.** Abaxial surface of leaf-blade with visible papillae with thick bases on veins; LS corolla internally with a ring of short hairs in the middle of the corolla tube *G. verbenoides*
- 10'.** Abaxial surface of leaf-blade without visible papillae; LS corolla internally with a ring of slender short hairs in the middle of the corolla tube, and thick long hairs in the middle of the corolla lobes *G. laxa*
- 11.** Leaves with only the primary vein visible *G. brasiliensis*
- 11'.** Leaves with the secondary veins furrowed on the adaxial surface and marked on the abaxial surface 12
- 12.** Stems decumbent, stoloniferous; inflorescence with partial inflorescences pauciflorous, fasciculate *G. hispidula*
- 12'.** Stems erect, without stolons; inflorescence with partial inflorescences multiflorous, subglomeriform and condensed *G. dichasia*

Galianthe brasiliensis (Spreng.) E.L. Cabral & Bacigalupo, Ann. Missouri Bot. Gard. 84(4): 861-865. 1997. Fig. 4A-F

(For synonymy and commentaries about the types see Cabral & Bacigalupo 1997).

Shrub erect, branched, 0.25-1.5 m tall, with xylopodium; stems tetragonal, angles narrowly winged. Stipular sheath hispidulous, with 5-7 fimbriae. Leaves frequently pseudoverticillate, leaf blades elliptic or obovate, 3-35 × 0.7-11 mm, middle vein glabrous on the adaxial surface and scabridulous on the abaxial surface, with only primary nerve visible. Inflorescences thyrsoid-spiciform, with floral node of fasciculate flowers of main and secondary branches. Flowers shortly pedicellate; hypanthium turbinate, hispidulous; calyx 4-lobed, with 2 large lobes; corolla internally with ring of moniliform hairs. LS flower with corolla 1.9-2.2 mm long. SS flower with corolla 2.7 mm long. Capsule 1.5 (2.5) mm long, turbinate, dorsoventrally compressed, hispidulous, with indehiscent valves. Seeds 1.8-2 mm long, ventral face with a small strophiole; testa reticulate.

Distribution, habitat, and phenology: Brazil (BA, MG, PR, RJ, RS, SC, and SP), Paraguay, Uruguay, and Argentina. This species grows in low grasslands, margins of rivers and streams, and edges and interiors of forests. Flowering and fruiting throughout the year.

Table 2. Morphological comparison between *Galianthe riograndensis* sp. nov. and *G. equisetoides*.

	<i>G. riograndensis</i>	<i>G. equisetoides</i>
Number of leaves per node and size (mm)	3–4 leaves, 30–100 × 7–13	2–3 leaves, 26.6–49.7 × 0.5–1.1
Brachyblasts	Ausent, verticillate leaves	Present, pseudoverticillate leaves
Stipular sheath length (mm)	9–14	3.8–4.7
Number and length of the fimbriae (mm)	3–6 fimbriae; 5–7	5–6 fimbriae, 2.8–5.6
Leaf shape	Elliptic or narrowly elliptic	Linear or filiform
Leaf venation	Visible primary and 2–3 secondary veins	Inconspicuous primary and secondary veins
Flower length (mm)	SS flowers: 8.5–10 LS flowers: 8.5–9.6	SS flowers: 5–6 LS flowers: 4.5–5
Inner corolla indument	A fringe of moniliform hairs disposed from the middle of the corolla tube to the lower half of the corolla lobes	A ring of moniliform hairs in the corolla tube
Style	Divided	Not divided
Capsule length (mm)	Capsule 4.5–6	Capsule 2.2–3.7
Seed length (mm)	Seeds 3–3.5	Seeds 2.5–3
Habitat	Hillsides with basaltic rocky fields and seasonal forest	Low and floodable savannas

specimens in the past. For this reason, several epithet and subspecific names have been proposed and are currently synonyms of *G. centranthoides* (Cabral 2009).

Specimens examined: **Rio Grande do Sul:** Arroio dos Ratos, 28 October 1977, K. Hagelund 11989 (ICN); Caçapava, December 1823, Sellow 1517 (R); Campo Bonito, BR 101, km 6, 10 February 1983, A. Galianthe chodatiana (Standl.) E. L. Cabral Bol. Soc. Argent. Bot. 27(34): 242. 1991 [1992]. Fig. 5A–F

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, 0.30–1 m tall, with xylopodium; stem subtetragonal, glabrous. Stipular sheath with a brief extension above the separation of the pair of leaves, 3–5 mm, pilose, with 6–7 fimbriae, glabrous. Leaves

pseudoverticillate, with brachyblasts, leaf blades elliptic, 30–45 × 5–15 mm, discolored, darker in bundle, abaxial surface pubescent or with scattered hairs on veins, with 3 (4) pairs of secondary veins. Inflorescence thyrsoid terminal only in the main branches, long pedunculate, 20–35 cm. Flowers with hypanthium turbinate, pilose or with scarce scattered hairs; calyx 4-lobed, pilose with intercalary colleters; corolla 4.5–7 mm, externally micropapillate. SS flower with corolla 4.56–8.0 mm long, internally with hairs in base of the corolla lobes and in inferior third of the corolla tube. LS flower with corolla 5–7 mm long, internally with thick hairs in corolla lobes, and a dense ring of thinner hairs in middle of corolla tube. Capsule 2.5–4.3 mm, glabrous, with dehiscent valves. Seeds 3–3.5 mm long, compressed, with winged edges at poles.

Distribution, habitat, and phenology: Brazil (PR, SC, and RS). Frequently found in open grasslands between 700–900 m. Flowering from October and fruiting from January to February.

Observations: Recorded only for the states of Paraná and Santa Catarina, Brazil. From recent collections and study of additional herbarium material, this species is now reported for the first time from the state of Rio Grande do Sul, extending its distribution to southern Brazil.

Specimens examined: **Rio Grande do Sul:** Barracão, na rodovia para Lagoa Vermelha, 7 February 1988, N. Silveira & D. Farias filho 5447 (HAS); Esmeraldalda, 25 November 1983, G. Hiltl. 1454 (CTES, HAS); Vacaria, ruta 116, 28°31'45.94" S 50°57'5.15" O, 10 December 2016, J. E. Florentín et al. 29 (CTES, CTBS).

Galianthe dichasia (Sucre & Costa) E.L. Cabral, Bol. Soc. Argent. Bot. 27(3–4): 242. 1991. Fig. 5G–K

(For synonymy and commentaries about the types see Cabral & Bacigalupo 1997)

Subshrub 50–80 cm tall; stems rooting at basal nodes, tetragonal, fistulose, conspicuously winged at each angle, retrorse-fimbriate on margin. Stipular sheath pilose, with 5–7

A synopsis of *Galianthe* (Rubiaceae) in Rio Grande do Sul, Southern Brazil, and a new endemic species from Serra Geral

fimbriae. Leaves pseudoverticillate, with leafy brachyblasts, leaf blades elliptic, 15–60 × 6–20 mm, pilose, scaberulous or subglabrous on both adaxial and abaxial surfaces, 3–5 pairs of secondary veins. Inflorescence cymose, dichasial to monochasial, with partial inflorescences congested on main and secondary branches. Flowers with obconic, glabrous hypanthium; calyx 4-lobed; corolla externally micropapillate, internally with two rings of moniliform hairs, one in corolla tube and other with thick hairs on base of corolla lobes; SS flower with corolla 4–5.2 mm long; LS flower with corolla 3–7.5 mm long. Capsule 2.5–3.5 mm long, with indehiscent valves. Seeds 2 mm long, with strophiole partially covering the ventral surface.

Distribution, habitat, and phenology: Southern Brazil (PR, SC, and RS), Paraguay, Uruguay, and Argentina. This species grows in lowlands, marshy soils, and shore side of inland bodies of freshwater. Flowering from September to May.

Observations: We corroborate that the material recorded and analyzed as *Diodia cymosa* (*Galianthe cymosa*) in Rambo (1962) and Porto (1977), corresponds to *G. dichasia*.

Specimens examined: Rio Grande do Sul: Bom Jesus, 13 January 1941, B. Rambo 8521 (PACA); Cambará do Sul, February 1948, B. Rambo 36712 (PACA); Caxias do Sul, 8 February 1955, B. Rambo 56689 (PACA); Farroupilha, 7 February 1950, B. Rambo 45708 (CTES); idem 14 January 1957, B. Rambo s/n (HAS 71275); Iljuizinho, 30 January 1942, B. Rambo 9961 (PACA); São Leopoldo, 1907, S. Theissen s/n (PACA); Torres, Lagoa dos Quadros, 21 February 1950, B. Rambo 45992 (CTES, LIL).

Galianthe equisetoides (Cham. & Schleidl.) E.L. Cabral, Bol. Soc. Argent. Bot. 27: 242. 1991. *Borreria equisetoides* Cham. & Schleidl. Type: Brazil: Brasilia meridionalis, 1814–1831, Sellow s.n. [Lectotype here designated: HAL-98351 (photo!)]. Fig. 6A–E.

(For synonymy see Cabral & Bacigalupo 2009)

Subshrub erect, 0.60–1.50 m tall, with xylopodium; stems cylindrical or subtetragonal, fistulose, glabrous, constricted at nodes. Stipular sheath glabrous, with 5–6 fimbriae. Leaves 2(–3) pseudoverticillate, with leafy brachyblasts, leaf blades linear or filiform, 15–40 × 5 mm, glabrous, secondary veins inconspicuous. Inflorescence corymbiform, terminal only on main branches. Flowers with turbinate glabrous hypanthium; calyx 4-lobed, glabrous with intercalary colleters; corolla externally papillate; SS flower with corolla 5–6 mm long, internally with ring of moniliform hairs in corolla tube; LS flower with corolla 4.5–5 mm long, internally with ring of thin short moniliform hairs in corolla tube, and ring of thick long hairs in corolla lobes. Capsule 2.2–3.7 mm long, subcylindrical, glabrous, with dehiscent valves. Seeds 2.5–3 mm long, persistent strophiole.

Distribution, habitat and phenology: Brazil (PR and RS), and Argentina. It grows in low and floodable savannas. Flowering from October to February and fruiting from March to June.

Observations: Cabral (2009) designated a neotype for *Borreria equisetoides*, basonym of this species, assuming that the specimen of *Sellow s.n.*, mentioned in the protologue was deposited in the herbarium B and was destroyed. However, currently the database of JSTOR possesses a digitalized specimen of *Sellow s.n.* deposited in the HAL herbarium, which is here designated as lectotype. It should be noted that this specimen is sterile, nonetheless the stem possesses contractile nodes, linear leaves and inconspicuous secondary veins, all of which are diagnostic characters that differentiate *Galianthe equisetoides*.

On the other hand, Abruzzi 1644 (HAS) was incorrectly selected as neotype of the basonym *Borreria equisetoides* (=*G. equisetoides*), but because of the 3–4 verticillate leaves, conspicuous secondary veins, larger flowers, long-bifid style, and also by the differences in habitat, the specimen is considered as a paratype of *G. riograndensis*.

Specimens examined: Rio Grande do Sul: Arroio Porto, 08 December 1976, S.T. S. Miotti et al. 165 (ICN); Costa do Cadeia, Triunfo, April 1983, M. Sobral 1657 (BR); Guaíba, 28 October 1970, B. Irgang s/n. (ICN); Guaíba, October 1970, B. Irgang 7834 (ICN); Montenegro, Pareci Novo, 25 November 1945, E. Henz 33227 (CTES, PACA); Montenegro, Prope flumen Cai, 27 December 1949, A. Sehnem 4459 (PACA); Montenegro, Pareci, 25 November 1945, E. Henz s/n (PACA); Porto Alegre, B. Rambo 51549 (PACA); São Pedro do Sul, 27 February 2006, L. P. Deble & A. S. Oliveira s/n (HDCF); Tapes, 30 December 1974, M. L. Porto et al. 1378 (ICN); Triunfo, 22 January 1964, E. Pereira 8526 (RB).

Galianthe fastigiata Griseb., Symb. Fl. Argent. 24:157.1879. Fig. 6F–K

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, 0.25–1.20 m tall, with xylopodium; stems fistulose, cylindrical or subtetragonal, glabrous. Stipular sheath glabrous, with 5–7 fimbriae. Leaves opposite, without axillary brachyblasts, sessile, leaf blades narrowly elliptic or linear, 20–110 × 2–25 mm, glabrous, secondary veins inconspicuous. Inflorescences terminal only on main branch. Flowers sessile or shortly pedunculate; hypanthium turbinate, glabrous; calyx 4-lobed, with intercalary colleters; corolla externally micropapillate; SS flower with corolla 3.5–6.2 mm long, internally with thin moniliform hairs in corolla tube, and thick longer hairs in corolla lobes; LS flower with corolla 3.7–6 mm long, internally with dense hairs, except the lower third of corolla tube. Capsule 3.5–4.5 mm long, turbinate, glabrous, with dehiscent valves. Seeds 2.5–3.2 mm long, subelliptic, with persistent strophiole; testa scrobiculate.

Distribution, habitat and phenology: Brazil (RS and SC), Argentina, eastern Paraguay and Uruguay. It is common in sandy and rocky soils, in palm groves of *Butia* and roadsides. Re-grow after burning. Flowering from October to February, fruiting from March to June.

Galianthe hispidula (A. Rich. ex DC.) E. L. Cabral & Bacigalupo, Ann. Missouri Bot. Gard. 84(4): 870-871. 1997.
Fig. 7A-F

(For synonymy and commentaries about the types see Cabral & Bacigalupo 1997)

Subshrub with long stolons, 30-60 cm tall; decumbent stems; and simple flowering branches tetragonal, winged, glabrous or pilose on the angles. Stipular sheath scabridulous or pilose, with 5-9 fimbriae. Leaves opposite, pseudopetiolate, leaf blades elliptic, 35-100×15-35 mm, discolorous, with 5-8 pairs of slightly curved subparallel secondary veins. Inflorescences cymose, monochasial to pleiochasial, partial inflorescences fasciculate and congested, terminal on main and secondary branches. Flowers with turbinate hypanthium; calyx 4-lobed, with 2 large lobes; corolla externally micropapillate; SS flower with corolla 2.9-4.64 mm long, internally with sparse hairs in corolla tube and at base of corolla lobes; LS flower with corolla 3.24-4.26 mm long, internally with thick moniliform hairs in corolla lobes, and thin hairs in corolla tube. Capsule 1.6-2 mm long, subhemispheric, scabridulous or glabrous, with indehiscent valves. Seeds 1.4-1.6 mm long, with persistent strophiole.

Distribution, habitat, and phenology: Brazil (MG, PR, RJ, SC, SP, and RS), eastern Paraguay and northeastern Argentina. Grows in understory with abundant litterfall

Galianthe latistipula E.L. Cabral, Bonplandia 6(4):14-18. 1993. Fig. 7G-J

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, 45–95 cm tall, with xilopodium; 1(2-3) stems per plant, without lateral branches, stems fistulose, cylindrical or subtetragonal, glabrous. Stipular sheath extended above insertion of leaves, irregular margin with remarkable central fimbria, triangular, acuminate, and shorter lateral fimbriae. Leaves 6-10 pseudoverticillate, with leafy brachyblasts, sessile, leaf blades lanceolate, elliptic-lanceolate, 15–60 × 3–15 mm, glabrous, inconspicuous secondary veins on adaxial surface, slightly marked on the abaxial surface. Inflorescence corymbiform, terminal only on main branches. Flowers with turbinate hypanthium, glabrous; calyx 4-lobed, with intercalar colleters; corolla externally glabrous; SS and LS flowers with similar corolla size. Capsule 2.5–3.5 mm long, turbinated, glabrous, with dehiscent valves. Seeds 2–2.7 mm long, compressed, with slightly alate apex, with a caducous strophiole.

Distribution, habitat, and phenology: Brazil (RS and SC). This species lives in high rocky fields between 1000-1800 m elevation in the Meridional high plateau (Fernandes & Bezerra 1990), also called “Planalto riograndense” (Rambo 1956). Flowering and fruiting from December to March.

Galianthe laxa (Cham. & Schldl.) E. L. Cabral, Bol. Soc. Argent. Bot. 27: 244-245. 1991. Fig. 8A-E

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub scandent 0.5-1.7 m tall, without xilopodium; stems tetragonal glabrous, puberulous or pubescent. Stipular sheath pubescent, with 5-12 fimbriae. Leaves pseudoverticillate, with leafy brachyblasts, pseudopeciollate, leaf blades elliptic or oval-elliptic, 20–100 × 6–30 mm, discolorous, glabrous or with sparse hairs on adaxial surface and pubescent on abaxial surface, with 4-6 pairs of secondary veins arched towards apex, furrowed in adaxial surface, and prominent in abaxial surface. Inflorescences thyrsoid, lax, rarely compressed. Flowers, with turbinated hypanthium, glabrous, puberulous or pubescent; calyx 4-lobed, with intercalar colleters; corolla externally papillate; SS flower with corolla 3-4 mm long, internally with a fringe of thin moniliform hairs in corolla tube; LS flower with corolla 2.7-4 mm long, internally with ring of short thin moniliform hairs in middle of corolla tube, and ring of thick hairs in middle of corolla lobes. Capsule 1.7-3 mm long, turbinated, glabrous or with sparse hairs, with dehiscent valves. Seeds 1.7–2.5 mm long, elliptic, with caducous strophiole, rarely persistent; testa foveolate.

Distribution, habitat, and phenology: Brazil (MS, PR, RS, SC, and SP), eastern Paraguay, Bolivia, Argentina, and Uruguay. It is one of the most widely distributed species, occurring between 16° and 25° S. It lives at different elevations in low fields, on the banks of streams and rivers, in open places or inside forests. Along with *Galianthe brasiliensis*, they are the two southernmost species, reaching the delta of Paraná, Buenos Aires. Flowering from November to February and fruiting from March to August.

Observations: *Galianthe laxa* is represented in Rio Grande do Sul by the subsp. *laxa*. This subspecies is highly variable in habit, indumentum, form, size and texture of leaves, development and size of inflorescences.

Galianthe thalictroides (K. Schum.) E.L. Cabral. Bol. Soc. Argent. Bot. 27(3-4): 246. 1991. Fig. 8F-K

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, branched, 0.6–1.2 m tall, with 3–5 main branches with numerous opposite and secondary branches, xylopodium well-developed; often forms dense scrubs; stems subtetragonal, glabrous or papillate. Stipular sheath glabrous or puberulous, with 1–5 fimbriae. Leaves pseudoverticillate, with brachyblasts, leaf blades linear or narrowly elliptic, 8–25 × 7–2 mm, margin revolute, glabrous or papillate, conspicuous primary veins and inconspicuous secondary veins. Inflorescences thyrsoid corymbiform, pedunculated, terminal only on main branch. Flowers with turbinate hypanthium, glabrous; calyx 4-lobed, glabrous, with intercalary colleters; corolla externally papillate; SS flower with corolla 5.5–6.2 mm long, internally with ring of moniliform hairs in corolla tube, and sparse hairs in corolla lobes; LS flower with corolla 3.7–5 mm long, internally with ring of thin moniliform hairs in corolla tube, and thick hairs in corolla lobes. Capsule 3–5 mm long, with dehiscent valves. Seeds 2–3.5 mm long, dorsoventrally compressed, irregularly winged, ventral surface partially covered by strophiole.

Distribution, habitat and phenology: Brazil (RS, SC, PR, and SP), northeast Argentina, eastern Paraguay and Uruguay. This species grows in highland grasslands, lateritic soils, modified lands, roadsides. Flowering from November to January and fruiting from February to March.

Galianthe valerianoides (Cham. & Schltdl.) Griseb., Symb. Fl. Argent. 24:157. 1879. (For synonymy and commentaries about the types see Cabral 2009)

(For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, 0.8–2.5 m tall, with xylopodium; stems tetragonal, fistulose, scabrous, rarely glabrous, angles

with retrorse hairs. Stipular sheath pubescent, with 9–11 fimbriae. Leaves pseudoverticillate, with brachyblasts, leaf blades narrowly elliptic or oblong, 35–115 × 10–25 mm, plicate-nervose, scabridous, with 4–6 pairs of subparallel veins. Inflorescence terminal on main branch. Flower with micropapillate hypanthium, sometimes pilose; calyx 4-lobed, papillate, intercalary colleters; corolla externally papillate; SS flower with corolla 3.4–4.5 mm long, internally a fringe of moniliform hairs in corolla tube and in base of the corolla lobes; LS flower internally with ring of thin short moniliform hairs in corolla tube, and thicker longer hairs in corolla lobes. Capsule 3.7–4.2 mm long, subcylindrical, glabrous, sometimes with sparse hairs, with dehiscent valves. Seeds 2.5–3.5 mm long, dorsoventrally compressed, unequally winged, wings larger at the ends; testa finely foveolate

Distribution, habitat, and phenology: Brazil (DF, GO, MS, MG, PR, RS, SC, and SP), northeast Argentina, eastern Paraguay. It lives in swamps, low places, and marshes and streams. Flowering from October to January, and fruiting from February to July.

Specimens examined: Rio Grande do Sul: Bom Jesus, 4 December 1971, *J. Lindeman s/n* (ICN 9460); Caixas do Sul, Vila Oliva, 8 February 1955, *B. Rambo* 53473 (PACA); Canela, February 1986, *M. Galianthe verbenoides (Cham. & Schltdl.) Griseb., Symb. Fl. Argent. 24:157. 1879. (For synonymy and commentaries about the types see Cabral 2009)

Subshrub erect, branched, 0.6–1 m tall, with opposite lateral branches well-developed, without xylopodium; stems tetragonal or subcylindrical, glabrous, sometimes with hairs or aculeate or mammillate papillae near stipular sheath. Stipular sheath glabrescent or pubescent, with 10–11 fimbriae. Leaves pseudoverticillate, with brachyblast pseudopeciolate, leaf blades oblong-elliptic, 15–120 × 3–17 mm, discolorous, glabrescent or scabridulous, abaxial surface with aculeate papillae of thick base on the veins, especially on primary vein, with 3–6 pairs of secondary veins subopposite, in converging arcs toward apex. Inflorescences thyrsoid, terminal on main and secondary branches. Flowers with turbinate hypanthium, glabrous; calyx 4-lobed, glabrous, with intercalary colleters; corolla externally micropapillate; SS flower with corolla (2.5) 4.5–4.7 mm long, internally with ring of moniliform hairs in middle of corolla tube; LS flower with corolla 3–3.2 mm long, internally

with short moniliform hairs in middle of corolla tube, and sparse hairs in base of the corolla lobes. Capsule 1.7–2 mm long, subglobose, glabrous, with dehiscent valves. Seeds 1.5–1.7 mm long, subcylindrical, strophiole persistent; testa scrobiculate.

Distribution, habitat, and phenology: Brazil (PR, RS, and SC). It is very common in roadsides, edges of streams, and in highlands. Flowering and fruiting from November to April.

Specimens examined: Rio Grande do Sul: Arroio dos Ratos, 30 January 1985, E. Cabral 486 (CTES); Bom Jesus, 14 January 1942, B. Rambo 8690 (PACA); Bom Jesus, Serra da Rocinha, s/d., B.
